HOW I USED AI

Cheerio Resolve | Assignment A | 15 October 2026

My approach

I used AI to move faster on research synthesis, option comparison, drafting and frontend implementation. I did not treat the first polished answer as proof. The most useful work came from challenging generic suggestions, checking what public evidence supported, and narrowing the product to something the prototype could actually demonstrate.

1. Tools used

Tool	How I used it
ChatGPT	Organized the public product research, compared solution approaches, challenged the original concept, helped structure the proposal and model, and drafted the frontend implementation brief.
Antigravity	Used to build the interactive frontend from the product specification. The local prototype uses simulated data; it is not connected to Cheerio production systems.
Word and spreadsheet tools	Used to turn the product decision into a concise proposal and a formula driven cost, billing and audit model.

2. Three prompt patterns that helped

The excerpts below summarize the actual instructions from the project conversation in cleaned, shorter form. They are not presented as exact full transcripts. I will attach the relevant AI chat link or screenshots from the original conversations as the assignment requests.

PROMPT 1 | RESEARCH BEFORE CHOOSING

Prompt excerpt

Compare the support problem areas using Cheerio's public documentation. Separate documented facts from inference and unknowns, and identify what a new solution could do beyond repeating help articles.

What changed because of it: I treated Cheerio's existing help, onboarding and MCP capabilities as part of the design constraint. That ruled out a generic documentation chatbot as the main idea. I kept a clear distinction between published facts and unresolved questions, especially because I could not inspect a live Cheerio workspace.

PROMPT 2 | CHALLENGE THE PRODUCT IDEA

Prompt excerpt

Go deeper on whether the chosen direction is actually differentiated. Improve the idea without claiming it is unprecedented, and make the product value and first use case explicit.

What changed because of it: The concept became an Evidence to Resolution Loop: investigate with available evidence, guide the correction, verify the relevant outcome, create a Resolution Passport, and propose reusable fixes for human review. Resolution Intelligence became a way to flag recurring patterns for investigation, not a claim that the system can automatically diagnose product defects.

PROMPT 3 | MAKE THE PROTOTYPE PROVE THE PRODUCT

Prompt excerpt

Improve the existing prototype's visualization and interaction without reframing the product. Make the orchestration show what happens through diagnosis, deterministic checks, selective AI assistance, verification and escalation.

What changed because of it: The prototype specification focused on a connected investigation journey and a visible orchestration pipeline instead of a collection of unrelated screens. The resulting UI shows User Context, Evidence Inspector, Rule Engine, AI Assist, Guided Fix, Verification, Passport, Fix Memory and Human Handoff nodes.

A WEAKER APPROACH AND HOW I CORRECTED IT

3. One approach that did not work well

The weak prompt pattern

"Make it the best possible, with more animations and a much more impressive interface."

Why it was weak: this was too open ended. It encouraged adding visual effects and extra elements without first asking whether they made the core product mechanism easier to understand. It also risked spending time on polish while the required deliverables and end to end interaction still needed validation.

What I changed

I constrained the next iteration to the existing application. The goal became making the orchestration respond to the real demo state, keeping the Resolution Passport consistent with the investigation, making the assistant contextual, supporting light and dark themes, and testing the complete flows. I also decided to stop adding features once the interface already communicated the concept, and to focus on correctness and submission readiness.

4. Where AI was weak and how I checked it

Weakness	How I responded
It can suggest a generic chatbot	I checked Cheerio's documented support, workflow and MCP capabilities. I selected a narrower evidence based resolution flow instead of proposing chat as the product itself.
It can turn missing documentation into a claimed product gap	I did not treat a missing public description as proof that Cheerio lacks a safeguard. I kept internal functionality and ticket frequency as questions for validation.
It can confuse explanation with resolution	I defined a successful outcome around a relevant state change or clear completion evidence, and made "unable to verify" a valid result.
It can make estimates look like facts	I labelled support volume, eligible share, resolution rate, human cost, model usage and pricing as assumptions. The spreadsheet exposes these inputs for review.
It can overdesign	I cut back from a broad "more animations" direction and focused on state driven orchestration and a small set of important interactions.

5. Decisions and work I am responsible for

- I chose Assignment A and the support scaling problem rather than changing to the feature discovery assignment.
- I chose not to pitch a generic help centre chatbot because Cheerio already documents substantial support and AI capabilities.
- I narrowed the pilot to template and campaign troubleshooting because the journey can be demonstrated with bounded states, while keeping the final priority provisional until ticket data is available.
- I set the product boundary: deterministic checks first, AI only when useful, no unsupported claims, verification where possible, and human escalation when evidence or permissions run out.
- I chose the North Star around verified self service outcomes instead of the number of AI answers or tickets labelled deflected.
- I made the model assumptions editable and kept projected savings separate from real Cheerio economics.

AI contributed to the research synthesis, wording, modeling structure and implementation brief. I am not presenting the submission as entirely unaided. My responsibility is to check the evidence, understand and defend the trade offs, verify the calculations, test the prototype, and revise anything that is unsupported or inconsistent.

EVIDENCE TO ATTACH BEFORE SENDING

6. Prompt evidence and prototype record

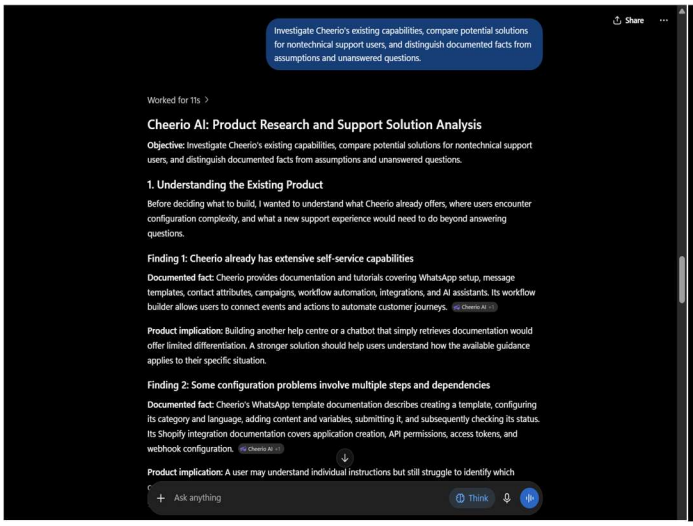

The assignment asks for AI chat links or screenshots of key prompts. This document is a prompt log; it is not itself a screenshot of the original chats. To make the evidence auditable, attach a genuine shared conversation URL or screenshots for the examples above, plus the original weak design prompt and the revised instruction.

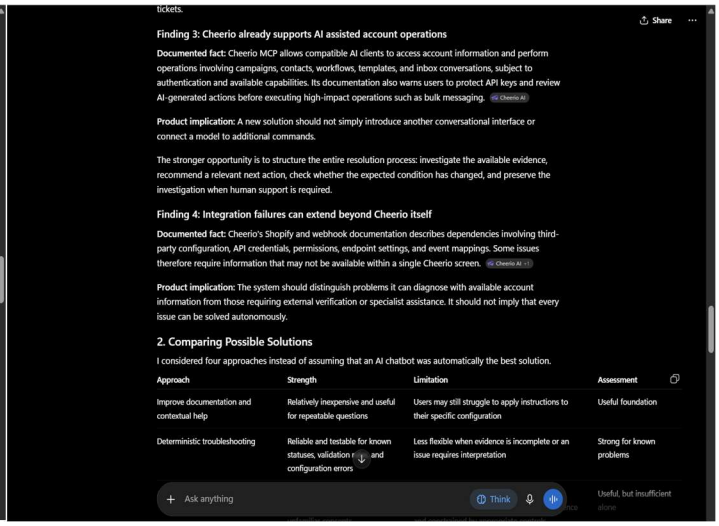

Evidence item	Evidence / Link
Research and product comparison	Everything added below (all links and screenshot's)
Concept refinement and Resolution Learning Loop	Everything added below
Antigravity frontend implementation	Everything added below
Weak prompt and correction	Everything added below

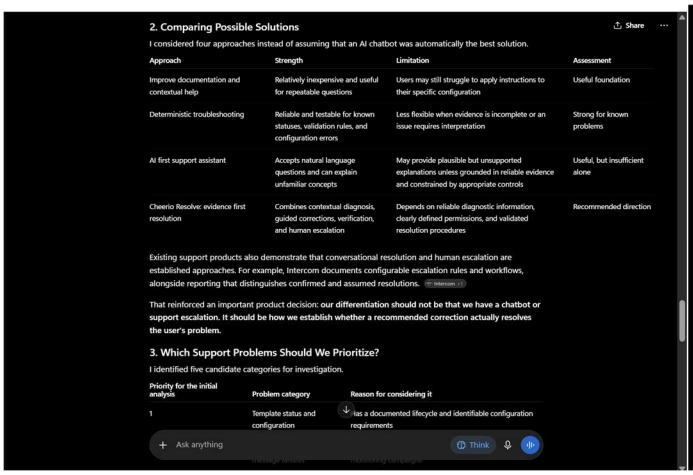

6.1. Prompt 1: Research and product comparison

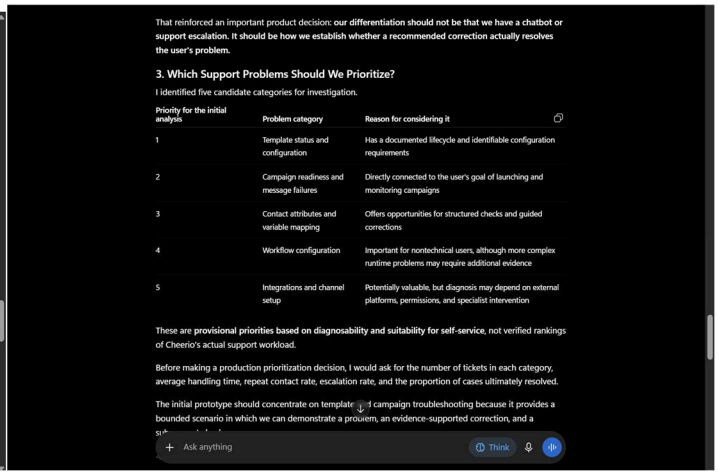

Prompt summary: Investigate Cheerio's existing capabilities, compare potential solutions for nontechnical support users, and distinguish documented facts from assumptions and unanswered questions.

What worked: The research showed why a generic support chatbot would be insufficiently differentiated. I narrowed the initial scope to template and campaign troubleshooting, where a guided diagnostic process and observable outcome could be demonstrated.

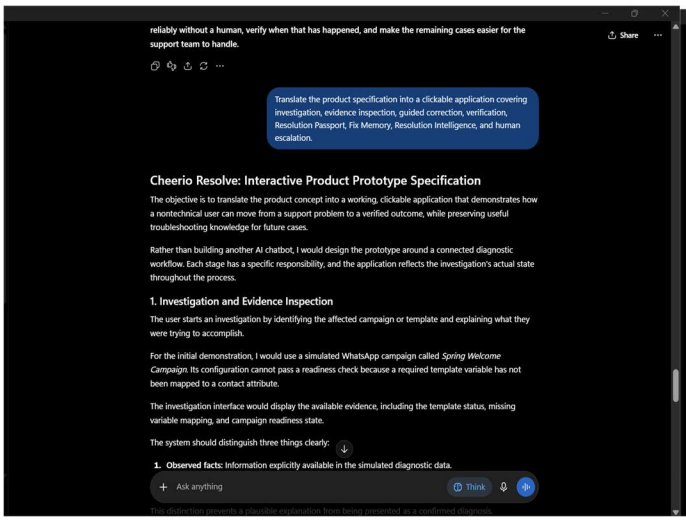

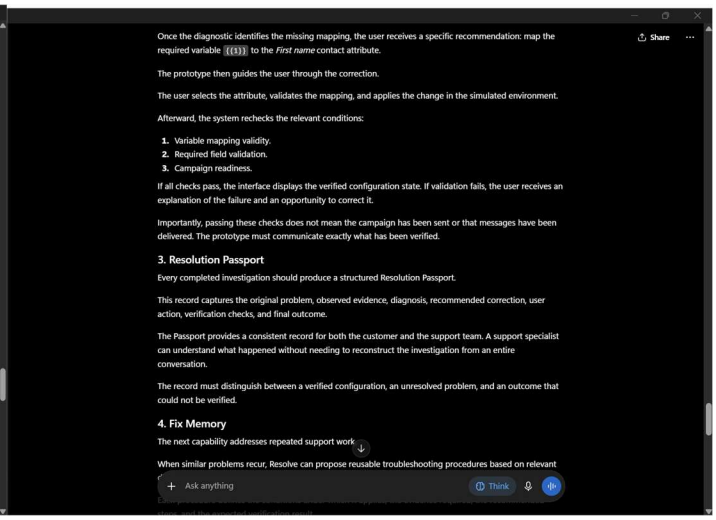

6.2. Prompt 2: Concept refinement

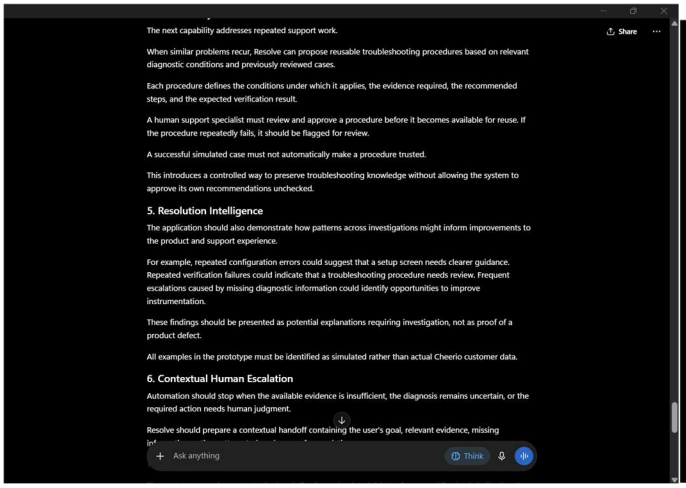

Prompt summary: Develop a support resolution experience that inspects available evidence, recommends appropriate actions, verifies outcomes, and escalates cases when reliable resolution is not possible. Explore how successful procedures could become reusable troubleshooting knowledge.

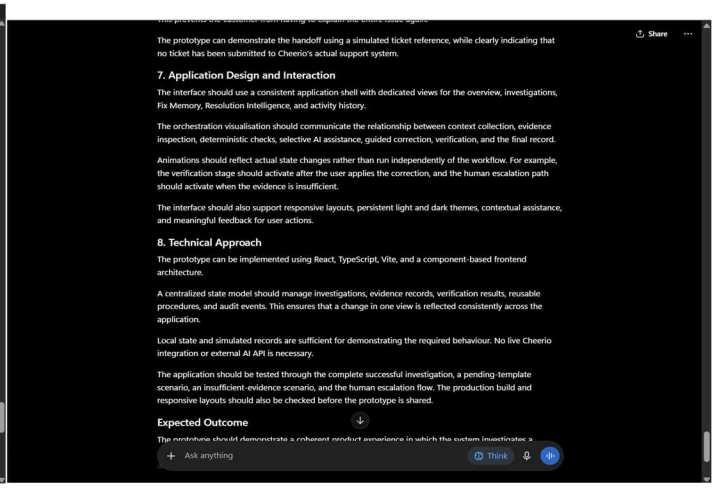

What worked: This led to the Evidence to Resolution Loop, with the Resolution Passport recording evidence, actions, and outcomes, and Fix Memory supporting reusable procedures subject to human review.

My decision: I retained deterministic checks for known conditions, limited AI to useful interpretation and explanation, and made verification and human escalation explicit.

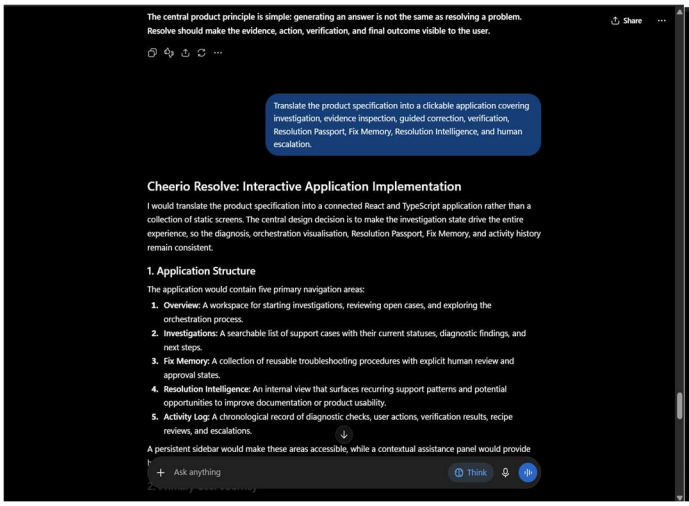

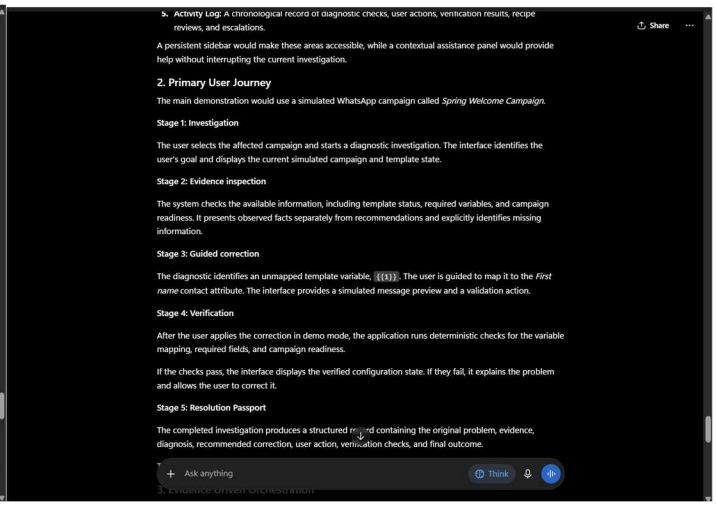

6.3. Prompt 3: Prototype implementation

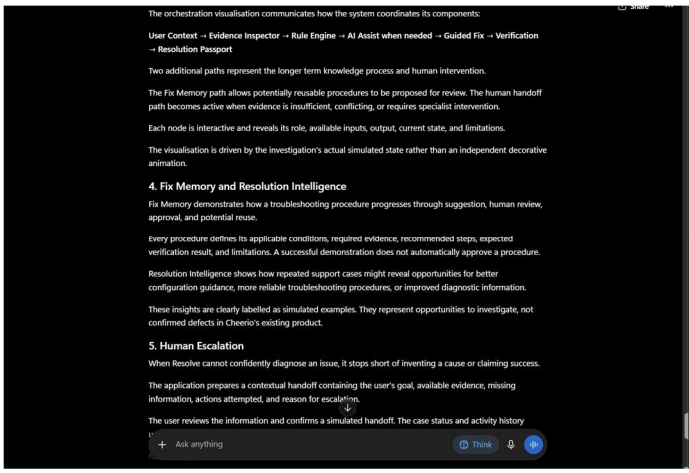

Prompt summary: Translate the product specification into a clickable application covering investigation, evidence inspection, guided correction, verification, Resolution Passport, Fix Memory, Resolution Intelligence, and human escalation.

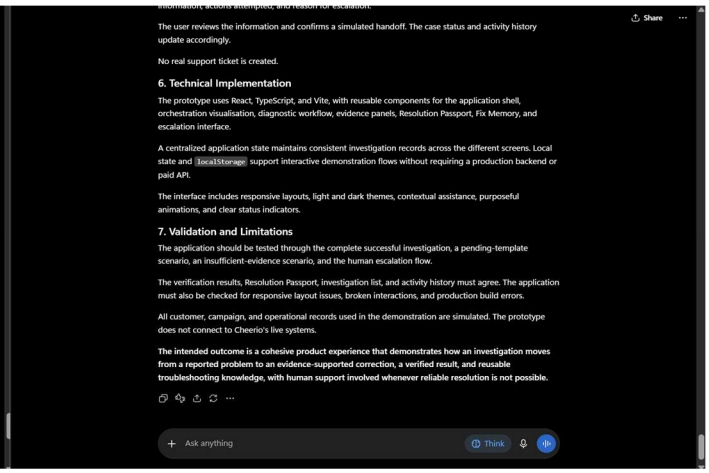

What worked: Antigravity helped implement the React, TypeScript, and Vite application. The resulting prototype includes an interactive orchestration visualization, guided troubleshooting, contextual assistance, and dedicated investigation and knowledge screens.

I reviewed the interface, refined the implementation requirements, committed the source code to GitHub, and deployed the frontend to Vercel. The prototype uses simulated data and does not connect to Cheerio's live systems.

Chat-GPT chat link : https://chatgpt.com/share/6ad0bc0e-07a0-83ee-8b6e-beca4c4907a7

Anti-Gravity link : Cheerio Resolve Product Prototype (Name of the conversation) but it is not allowing to share in the application (Here's the deployed version : https://cheerio-resolve.vercel.app/)

6.4. A weak approach and how I corrected it

The initial approach risked producing a broad AI support assistant without sufficiently establishing how it would differ from existing product capabilities.

The research also highlighted a weakness in treating missing information in public documentation as proof that a capability does not exist.

I corrected the approach by narrowing the problem, distinguishing documented facts from assumptions, defining explicit verification conditions, and requiring human intervention when the available evidence was insufficient.

The result was a more focused and testable product concept rather than another general-purpose chatbot.

6.5. Where AI was weak and how I evaluated its output

AI could suggest familiar chatbot patterns without adequately accounting for Cheerio's existing capabilities. I addressed this by examining the product research before selecting the solution.

AI could also present plausible explanations without sufficient evidence. I therefore made the product distinguish observed facts, recommendations, and unknowns, and prevented an answer from being counted as a verified resolution.

Finally, AI could make financial estimates appear more certain than their inputs justified. I kept operational volumes, handling costs, resolution rates, and other uncertain inputs as explicit assumptions rather than representing them as actual Cheerio data.

6.6. My contribution and product decisions

AI supported research, concept refinement, financial modelling, and frontend implementation. I evaluated its outputs rather than treating the first response as the final answer.

My main product decisions were to narrow the initial pilot to template and campaign troubleshooting, distinguish recommendations from verified outcomes, introduce the Resolution Passport, require human review before reusable procedures are approved, and keep the prototype separate from live Cheerio systems.

I also took responsibility for reviewing the interface, identifying limitations, and preparing the project for demonstration. The objective was to use AI to accelerate the work while retaining responsibility for the product direction, validation requirements, and final decisions.

7. Prototype status and limits

The current prototype demonstrates the interface and simulated troubleshooting journey. It must be described as a demo, not a live Cheerio integration. The primary scenario should be tested from diagnosis through correction, verification and Resolution Passport; the pending-template and insufficient-evidence paths should also be tested. Use actual screenshots from the running application, and do not claim that a check passed unless it was performed.

8. My rule for using AI on this assignment

The standard I used

AI helped me move faster, but I kept the product decision tied to evidence. If I could not establish a fact from the public documentation, I labelled it as an assumption or an open question. If the prototype could not verify an outcome, it should say so rather than present a confident answer.

That constraint is central to the idea itself: evidence first, action second, verification third, and human help when the system reaches the limits of what it can know or safely do.
