CHEERIO RESOLVE

From a support question to a verified outcome

Product proposal | 15 October 2026

The product thesis

The hard part is not always answering a support question. It is identifying the right cause, guiding a safe correction, and knowing whether the problem was actually fixed.

1. Who I am designing for

Primary user: a business owner or marketing operator who uses Cheerio but is not technical. They are setting up a WhatsApp template or campaign, see a status or error they do not understand, and need one reliable next step. The secondary user is the Cheerio support specialist who receives the case when self service is not enough.

I am treating this as a product hypothesis, not a claim about Cheerio's ticket mix. Its public onboarding material describes WhatsApp setup as technical and recommends help with initial configuration and workflows. Its public MCP documentation also describes a broad set of account data and actions, so a new support experience should do more than wrap help articles in a chat window.

2. Five issues I would investigate first

Rank	Issue to test	Why it belongs in the first review
1	Template pending or rejected	Explain the recorded status, show a supported next step, and avoid invented approval times.
2	Approved template, campaign or message fails	Inspect available campaign, message and channel evidence rather than assuming the template is the cause.
3	Chatbot or workflow behaves unexpectedly	Guide checks for triggers, variables and activation state; escalate if runtime evidence is unavailable.
4	WhatsApp channel or API setup is blocked	Walk through prerequisites, but route Meta account, verification and permission problems to a person.
5	Integration or contact data is not syncing	Check connection state, field mapping and available event evidence; escalate external credential or permission issues.

How I would prioritize

I would rank these initially by how consequential the problem is, whether the cause can be diagnosed from available evidence, and whether a fix can be verified. I would not pretend to know which issue is most frequent without support ticket data.

PRODUCT CHOICE

3. Options I considered

Option	What works	Trade off
Contextual help and better docs	Fast, predictable and inexpensive.	Still asks the user to interpret instructions; cannot establish that the account is fixed.
Rules based diagnostic checks	Reliable for known statuses and errors.	Limited when wording, telemetry or issue patterns fall outside known cases.
AI first support assistant	Handles flexible natural language.	Can answer without account evidence and spends model calls even on simple known states.
Cheerio Resolve	Evidence first routing, maintained playbooks, selective AI, outcome verification and a context rich handoff.	Needs reliable, authorized signals and ongoing quality review. This is the option I would pilot.

4. The solution I chose

Resolve starts from the task the user was trying to complete. It inspects the information it is allowed to see, uses explicit checks for known states, and calls a language model only when interpreting a user description or combining evidence is useful. It recommends one appropriate next step, then checks the relevant condition again when that evidence is available.

Stage	What happens
Context	Start from the selected campaign, template or reported problem.
Evidence	Show which signals were checked, what was observed and what is missing.
Route	Use a deterministic check or maintained troubleshooting recipe first; use AI selectively.
Guide	Explain one useful next step and its expected result.
Verify	Recheck the relevant condition. Mark the case unresolved or unable to verify if the evidence does not support success.
Preserve	Create a Resolution Passport and prepare a contextual handoff when a person is needed.

The distinctive loop: resolution to reusable knowledge

The Resolution Passport records the issue, observed evidence, recommended action, user action, verification and outcome. Across cases, Resolve can suggest recurring troubleshooting recipes for a support specialist to review. Approved recipes can then be reused only under stated conditions; repeated failures should send a recipe back for review. Resolution Intelligence can surface repeated patterns as opportunities to improve guidance or product design, not as automatic proof of a product defect.

Why this is more than a chatbot

The unit of value is a verified outcome, not a generated answer. The longer term opportunity is to make repeated support work easier to resolve while keeping reusable fixes under human review.

SCOPE, CONTROLS AND MEASUREMENT

5. What Resolve will and will not do

Boundary	Product behaviour
It will	Inspect authorized diagnostic signals; explain observed facts separately from hypotheses; guide known fixes; verify a relevant state change; record an outcome; and prepare a case summary for support.
It will not	Invent provider status or approval timelines; ask for credentials; claim that a message was delivered based on a configuration check; perform consequential live changes without authorization and confirmation; or treat an unverified answer as a resolution.

6. When a human must step in

- The required signal is missing, stale or contradictory after one focused clarification.
- The case needs Meta side action, account verification, permissions, billing judgement, a template appeal or another decision outside Resolve's authority.
- The recommended step fails verification or the same issue returns.
- The next action could send messages at scale, alter a live workflow, expose sensitive data, or spend money.
- The user asks for a person or the case raises a security, privacy or policy concern.

7. Success measures

North Star: Verified Self Service Resolution Rate

Eligible pilot issues completed without human intervention and backed by observable completion evidence, divided by all eligible issues entering the pilot. An answer, article click, abandoned conversation or unverified silence does not count as resolution.

Metric	Definition and purpose
Cost per verified resolution	Attributable model, infrastructure, QA and support costs divided by verified self service resolutions. Tests whether the approach is economical.
Repeat contact rate	Share of resolved labelled issues that reopen or recur for the same underlying reason within a defined window.
Escalation quality	Audit whether escalations were appropriate and whether cases needing a human were incorrectly handled automatically.

Three month pilot target

Proposed target: reach 40% Verified Self Service Resolution Rate for eligible template and campaign troubleshooting issues by the end of month three. This is a pilot target, not a measured result. Month 1 establishes the baseline and labels ticket categories; Month 2 tests a small cohort and audits failed diagnoses; Month 3 improves the recipes, verification and routing from observed outcomes. If the baseline shows 40% is unrealistic, revise the target transparently.

Guardrails: review false diagnoses, missed escalations, repeat contacts, latency, spend, abandonment and privacy or security incidents alongside the North Star.

VALIDATION AND OPERATING PLAN

8. How I would validate the idea

I would start with a narrow, read only pilot for template and campaign troubleshooting. Before building any live connector, I would confirm which status, error and channel readiness signals are available under real account permissions. I would evaluate the same test cases against three approaches: improved contextual help, an AI first assistant, and Resolve's evidence first routing. Cases should include pending templates, rejected templates with a known reason, approved templates with a campaign failure, insufficient evidence, and actions that require confirmation.

For each route I would measure verified outcome, time to resolution, cost per verified resolution, repeat contact and escalation quality. A support specialist should review a sample of claimed resolutions each week. We should use a staged rollout or holdout where feasible, and report sample size and limitations rather than treating a few successful demos as proof.

9. Billing, audit and cost discipline

I would keep predictable rule based checks inside the product experience and test an optional Resolve Plus add on for reviewed Fix Memory, audit history and richer resolution reporting. The working pricing hypothesis is $12 per business per month, with a small included allowance for AI assisted investigations. I would not charge per model call. The price and willingness to pay need customer validation.

The accompanying spreadsheet makes query volume, model usage, human handling, overhead, attach rate and price editable. Monthly controls include usage reconciliation, idempotent billing events, spend and retry alerts, allowance tracking, sample audits of verified outcomes, and a month end check that revenue covers attributable costs. Every financial figure is a scenario unless explicitly stated as an assignment input or published model price.

Open questions before launch

- Which ticket categories drive volume, handling time and repeat contacts?
- Which account and provider signals can be read reliably, under which user permissions?
- What existing internal support tools, audit logs and knowledge workflows would Resolve need to integrate with?
- What are the privacy, retention, security and confirmation requirements for reading or changing account state?

Research basis

The public documentation supports the problem context but does not establish internal ticket frequency, the absence of existing safeguards, actual resolution rates or actual support costs. The prototype uses simulated account records and does not connect to a live Cheerio account.
